Queues

Circular Queues

A Mazing Problem

Evaluation of Expressions

# Stack

- ❖ Definition: an ordered list in which insertions (also called push ed and adds) and deletions (also called pops and removes) are made **at one end called the *top***
- ❖ Given a stack  $S=(a_0, \dots, a_{n-1})$ 
  - $a_0$  is bottom element
  - $a_{n-1}$  is top element
  - $a_i$  is on top of element  $a_{i-1}$ ,  $0 < i < n$
- ❖ *Last-In-First-Out (LIFO)*
  - Insert the new element into the stack on the top end
  - We can only delete and get the top element of the stack

# Examples of Stack

# Examples of Stack

# System Stack

- ❖ Used by a program at run-time to process **function calls**.
- ❖ A program places an activation record or a **stack frame** on top of the system stack when it invokes a function.
- ❖ The previous stack (old) frame pointer points to the stack frame of the invoking function.
- ❖ The return address contains the location of the statement to be executed after the function terminates.
- ❖ If the function invokes another function, the local variables, except those declared static, and the parameters of the invoking function are added to its stack frame.

# System Stack

## ❖ System stack after function call

- fp: a pointer to current stack frame

(a) system stack before `a1` is invoked

(b) system stack after `a1` is invoked

# Stack ADT

**ADT** *Stack* is

**objects:** a finite ordered list with zero or more elements

**functions:**

for all  $stack \in Stack$ ,  $item \in element$ ,  $maxStackSize \in \text{positive integer}$

*Stack* CreateS( $maxStackSize$ ) ::=

create an empty stack whose maximum size is  $maxStackSize$

*Boolean* IsFull( $stack$ ,  $maxStackSize$ ) ::=

**if** (number of elements in  $stack == maxStackSize$ )

**return** TRUE

**else** return FALSE

*Stack* Push( $stack$ ,  $item$ ) ::=

**if** (IsFull( $stack$ ))  $stackFull$

**else** insert  $item$  into top of  $stack$  and **return**

*Boolean* IsEmpty( $stack$ ) ::=

**if** ( $stack == \text{CreateS}(maxStackSize)$ )

**return** TRUE

**else return** FALSE

*Element* Pop( $stack$ ) ::=

**if**(IsEmpty( $stack$ )) **return**

**else** remove and **return** the item on the top of the stack

# Stack Implementation

- ❖ Use a one-dimensional array, `stack[MAX_STACK_SIZE]`, where `MAX_STACK_SIZE` is the maximum number of entries

```
#define MAX_STACK_SIZE 100 /* maximum stack size */
typedef struct {
    int key;
    /* other fields */
} element;
element stack[MAX_STACK_SIZE];
int top = -1; /* denotes an empty stack */
void push( element item ) {
    /* add an item to the global stack */
    if ( top >= MAX_STACK_SIZE-1 )
        stackFull();
    stack[++top] = item;
}
element pop() {
    /* delete and return the top element from the stack */
    if ( top == -1 )
        return stackEmpty(); /* returns an error key */
    return stack[top--];
}
void stackFull() {
    fprintf( stderr, "Stack is full, cannot add element" );
    exit( EXIT_FAILURE );
}
```

# Example

```
main()
{
    element e,f;
    top = -1;
    e.key=3;    push(e);
    e.key=2;    push(e);
    f=pop();    top = 0;
    printf ("%d  %d\n", top, f.key);
}
```

# Queue

- ❖ Definition: an ordered list in which insertions (also called additions, puts, and pushes) and deletions (also called removals and pops) take place **at different ends**
  - all **insertions** take place one end, called the **rear**
  - all **deletions** take place at the opposite end, called the **front**
- ❖ *First-In-First-Out (FIFO) list: the first element inserted into a queue is the first element removed*
  - Insert the new element into the queue on the rear side
  - We can only delete/get the front element of the queue

# Examples of Queue

❖ In a shop, checkout line

❖ Job scheduling

- Frequently used in computer programming
- Job queue by an operating system
- The jobs are processed in the order they enter the system

# Queue

## ❖ Inserting and deleting elements in a queue

- Insert the elements A, B, C, D, E, in that order
- A is the first element we delete from the queue

# Queue ADT

**ADT** *Queue* is

**objects:** a finite ordered list with zero or more elements.

**functions:**

for all  $queue \in Queue$ ,  $item \in element$ ,  $maxQueueSize \in \text{positive integer}$

*Queue* CreateQ( $maxQueueSize$ ) ::=

create an empty queue whose maximum size is  $maxQueueSize$

*Boolean* IsFullQ( $queue$ ,  $maxQueueSize$ ) ::=

**if** (number of elements in  $queue == maxQueueSize$ )

**return** TRUE

**else return** FALSE

*Queue* AddQ( $queue$ ,  $item$ ) ::=

**if** (IsFullQ( $queue$ )) *queueFull*

**else** insert  $item$  at rear of  $queue$  and **return**  $queue$

*Boolean* IsEmptyQ( $queue$ ) ::=

**if** ( $queue == \text{CreateQ}(maxQueueSize)$ )

**return** TRUE

**else return** FALSE

*Element* DeleteQ( $queue$ ) ::=

**if** (IsEmptyQ( $queue$ )) **return**

**else** remove and **return** the  $item$  at front of queue

# Queue Implementation

- ❖ Using a one dimensional array and two variables, front and rear

```
Queue CreateQ(maxQueueSize) ::=
    #define MAX_QUEUE_SIZE 100 /* Maximum queue size */
    typedef struct {
        int key;
        /* other fields */
    } element;
    element queue[MAX_QUEUE_SIZE];
    int rear = -1;
    int front = -1;

Boolean IsEmpty(queue) ::= front == rear
Boolean IsFullQ(queue) ::= rear == MAX_QUEUE_SIZE-1

void addq( element item ) { /* add an item to the queue */
    if ( rear == MAX_QUEUE_SIZE-1 )
        queueFull( );
    queue[++rear] = item;
}

element deleteq() { /* remove element at the front of the queue */
    if ( front == rear )
        return queueEmpty( ); /* return an error key
*/
    return queue[++front];
}
```

# Example

```
main()
{
    element e,f;
    rear = front = -1;
    e.key=3;    addq(e); rear = 0, front = -1
    e.key=2;    addq(e); rear = 1, front = -1
    f=deleteq(); rear = 1, front = 0
    printf("%d %d %d\n", front, rear, f.key);
}
```

---	---	---

# Job Scheduling

## ❖ The creation of a job queue by an operating system

- If the operating system does not use priorities, then the jobs are processed in the order they enter the system

<i>front</i>	<i>rear</i>	<i>Q</i> [0]	<i>Q</i> [1]	<i>Q</i> [2]	<i>Q</i> [3]	Comments
-1	-1					queue is empty
-1	0	J1				Job 1 is added
-1	1	J1	J2			Job 2 is added
-1	2	J1	J2	J3		Job 3 is added
0	2		J2	J3		Job 1 is deleted
1	2			J3		Job 2 is deleted

Insertion and deletion from a sequential queue

## ❖ As jobs enter and leave the system, the queue gradually shifts to the right

- *queueFull* should move the entire queue to the left
  - Shifting an array is very time-consuming

# Circular Queue

- ❖ Regard the array `queue[ $MAX\_QUEUE\_SIZE$ ]` as circular
- ❖ The *front* index always points one position counterclockwise from the location of the front element in the queue
- ❖ The *rear* index points to the current end of the queue
- ❖ The position next to  $MAX\_QUEUE\_SIZE-1$  is 0, and the position that precedes 0 is  $MAX\_QUEUE\_SIZE-1$

(a) Initial

(b) Addition

(c) Deletion

# Circular Queue Implementation

```
void addq( element item )
{
    /* add an item to the queue */
    rear = (rear+1) % MAX_QUEUE_SIZE;

    /* permitting a maximum of MAX_QUEUE_SIZE-1 rather than MAX_QUEUE_SIZE elements*/
    if ( front == rear )
        queueFull();    /* print error and exit */
    queue[rear] = item;
}

element deleteq()
{
    /* remove front element from the queue */
    if( front == rear )
        return queueEmpty();
    front = (front+1) % MAX_QUEUE_SIZE;
    return queue[front];
}
```

# Example

	queue	[0]	[1]	[2]	[3]		front=0	rear=0
Add 3		[0]	[1]	[2]	[3]		front=0	rear=1
			3					
Add 5		[0]	[1]	[2]	[3]		front=0	rear=2
			3	5				
Add 7		[0]	[1]	[2]	[3]		front=0	rear=3
			3	5	7			
Add 8	Error: Queue is full!!!					front=0	<del>rear=0</del>	rear=3
		[0]	[1]	[2]	[3]			
Delete				5	7	front=1		rear=3
		[0]	[1]	[2]	[3]			
Add 10		10		5	7	front=1		rear=0

# A Mazing Problem

- To avoid checking for border conditions, surround the maze by a border of ones
- An  $m \times p$  maze will require an  $(m+2) \times (p+2)$  array
  - The entrance is at position  $[1][1]$  and the exit at  $[m][p]$

entrance

1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
```

exit

# A Mazing Problem

- ❖ We may have the chance to go in several directions
- ❖ Pick one and save our current position and the direction of the next move in the list (stack)
- ❖ If we have taken a false path, we can return and try another direction by getting the top element of the stack

# A Mazing Problem

## ❖ Implementation

```
typedef struct {  
    short int vert;  
    short int horiz;  
} offsets;  
offsets move[8]; /*array of moves for each direction*/
```

Name	Dir	move[dir].vert	move[dir].horiz
N	0	-1	0
NE	1	-1	1
E	2	0	1
SE	3	1	1
S	4	1	0
SW	5	1	-1
W	6	0	-1
NW	7	-1	-1

- ❖ If we are at position,  $maze[*row*][*col*]$  and wish to find the position of the next move,  $maze[*nextRow*][*nextCol*]$ , we set:
- $nextRow = row + move[dir].vert;$
  - $nextCol = col + move[dir].horiz;$

# A Mazing Problem

- ❖ Since we do not want to return to a previously tried path
  - We maintain a second two-dimensional array, *mark*, to record the maze positions already checked
  - Initialize this array's entries to zero
- ❖ Representation of the stack

```
#define MAX_STACK_SIZE 100 /*maximum stack size*/  
typedef struct {  
    short int row;  
    short int col;  
    short int dir;  
} element;  
element stack[MAX_STACK_SIZE];
```

# A Mazing Problem

## ❖ Initial maze algorithm

```
Initialize a stack to the maze's entrance coordinates and direction to north;
while ( stack is not empty ) {
    /* move to position at top of stack */
    <row, col, dir> = delete from top of stack;
    while ( there are more moves from current position ) {
        <nextRow, nextCol > = coordinates of next move;
        dir = direction of move;
        if ( (nextRow == EXIT_ROW) && (nextCol == EXIT_COL) )
            success;
        if ( maze[nextRow][nextCol] == 0 &&
            mark[nextRow][nextCol] == 0 ) {
            /* legal move and haven't been there */
            mark[nextRow][nextCol] = 1;
            /* save current position and direction */
            add <row, col, dir> to the top of the stack;
            row = nextRow;
            col  = nextCol;
            dir  = north;
        }
    }
}
printf("No path found\n");
```

    printf("%2d%5d\n", EXIT_ROW, EXIT_COL);
}
else printf("The maze does not have a path\n");
}
```

# Expressions

$((rear+1==front) \ || \ ((rear==MAX\_QUEUE\_SIZE-1) \ \&\& \ !front))$   
 $x = a/b - c+d*e - a*c$

❖ If we examine expression, we notice that it contains:

- operators: `==`, `+`, `-`, `||`, `&&`, `!`
- operands: `rear`, `front`, `MAX_QUEUE_SIZE`
- parentheses: `( )`

# Evaluation of Expressions

$$x = a/b - c + d * e - a * c$$

Let  $a=4$ ,  $b=c=2$ ,  $d=e=3$ . What is the  $x$  value and why?

- Precedence rule:  $*, / > +, -$
- Associativity rule: left to right
- Order can be changed by using parentheses.

# Evaluation of Expressions

- *Use fully parenthesized expression to get rid of the ambiguity.*
- *Use one pair of parentheses for each operator.*

$$x = a/b - c + d * e - a * c$$

$$x = (((a/b) - c) + (d * e)) - (a * c)$$

# Evaluation of Expressions

# Evaluation of Expressions

## ❖ Infix notation

- Binary operator is in-between its two operands
- e.g.  $a+b$ ,  $a-c*d$ ,  $(a+b)*c$

## ❖ Prefix notation (Polish notation)

- Operator appears before its operands – normally used in the arithmetic expressions of Lisp
- e.g.  $+ab$ ,  $-a*cd$ ,  $*+abc$

## ❖ Postfix notation

- Each operator appears after its operands - used by compiler
- e.g.  $ab+$ ,  $acd*-$ ,  $ab+c*$

# Evaluation of Expressions

Infix notation	Prefix notation	Postfix notation
$A+B*C$	$+A*BC$	$ABC*+$
$(A+B)*C$	$*+ABC$	$AB+C*$

In case of prefix and postfix notation, we don't need to use **parentheses** anymore.

# Infix to Postfix

1. Fully parenthesize the expression
2. Move all binary operators so that they replace their corresponding right parentheses
3. Delete all parentheses

e.g.      $A/B - C + D * E - A * C$

→      $(( ( (A/B) - C) + (D * E) ) - (A * C) )$

→      $(( (A/B) - C) + (D * E) ) (A * C) -$

→      $((A/B) - C) (D * E) + AC * -$

→      $(A/B) C - DE * + AC * -$

→      $AB / C - DE * + AC * -$

# Infix to Postfix

- ❖ Scan the infix expression from left to right
- ❖ Operands are passed to the output expression as they are encountered  
(Order of operands is same in infix and postfix expression)
- ❖ Save the operators until we know their correct placement and output the higher precedence operators first
- Stack operators as long as the precedence of the operator at the top of the stack is less than the precedence of the incoming operator
- ❖ Unstack when we reach the end of the expression

# Example

a+b\*c

[3]		a b c
[2]		
[1]	*	
[0]	+	

a+b\*c/d

[3]	
[2]	
[1]	*
[0]	+

abc d

a\*(b+c)\*d

[3]	
[2]	+
[1]	(
[0]	*

abc d

# Infix to Postfix

(incoming) left parenthesis is placed in the stack whenever it is found in the expression → **high precedence operator**

Stack operators until we reach the right parenthesis

(in stack) left parenthesis is unstacked only when its matching right parenthesis is found → **low precedence operator**

Right parenthesis is never placed in the stack

Two types of precedence :

*in-stack precedence(isp)* and *incoming precedence(icp)*

# Example

$a^*(b+c-d)\%e \rightarrow abc+d-*e\%$

[illegible]

# Infix to Postfix Implementation

```
#define MAX_STACK_SIZE 100  /* maximum stack size */
#define MAX_EXPR_SIZE 100  /* max size of expression */
typedef enum {lparen, rparen, plus, minus, times, divide,
              mod, eos, operand } precedence;

int stack[MAX_STACK_SIZE]; /* global stack */
char expr[MAX_EXPR_SIZE]; /* input string */

precedence stack[MAX_STACK_SIZE];
/* isp and icp arrays - index is value of precedence
lparen, rparen, plus, minus, times, divide, mod, eos */
/* isp: in stack precedence, icp: incoming precedence */
static int isp[] = { 0, 19, 12, 12, 13, 13, 13, 0 };
static int icp[] = { 20, 19, 12, 12, 13, 13, 13, 0 };
```

Left parenthesis has the highest priority when incoming, and the lowest priority while in the stack

# Infix to Postfix Implementation

```
void postfix(void)
{
    char symbol; precedence token; int n = 0;
    stack[0] = eos;
    for (token=getToken(&symbol,&n); token!=eos; token=getToken(&symbol,&n)){
        if (token == operand) printf("%c", symbol);
        else if (token == rparen){
            while (stack[top] != lparen) printToken(pop());
            pop(); /* discard the left parenthesis */
        }
        else {
            while (isp[stack[top]] >= icp[token]) printToken(pop());
            push(token);
        }
    }
    while ((token=pop()) != eos) printToken(token);
}
```

# Infix to Postfix Implementation

```
precedence getToken (char *symbol, int * n)
{
    *symbol = expr[(*n)++];
    switch (*symbol) {
        case '(' : return lparen;
        case ')' : return rparen;
        case '+' : return plus;
        case '-' : return minus;
        case '/' : return divide;
        case '*' : return times;
        case '%' : return mod;
        case ' ' : return eos;
        default : return operand;
    }
}
```

# Evaluating Postfix Expression

For convenience, let's assume that we use only binary operators and single-digit integers for an expression.

## ❖ Strategies

- 1) Place the operands on a stack until we find an operator
- 2) Remove the two operands
- 3) Perform the operation and place the result on a stack

# Evaluating Postfix Expression

- ❖ Scan the Postfix string from left to right
- ❖ Initialize an empty stack
- ❖ Place the operands on a stack until we find an operator
- ❖ If we find an operator,
  1. Remove, from the stack, the correct number of operands for the operator
  2. Perform the operation
  3. Place the result back on the stack
- ❖ Continue this fashion until we reach the end of the expression
- ❖ Then, remove the answer from the top of the stack

# Example

Assumptions:

- 1) Binary operators only
- 2) Single digit integer

62/3-42\*+

Token	Stack			Top
	[0]	[1]	[2]	
6	6			0
2	6	2		1
/	3			0
3	3	3		1
-	0			0
4	0	4		1
2	0	4	2	2
*	0	8		1
+	8			0

# Evaluating Postfix Expression

```
int eval(void){
    precedence token; char symbol; int op1,op2;
    int n = 0; top = -1;
    token = getToken(&symbol, &n);
    while (token != eos) {
        if (token==operand) push(symbol-'0');
        else {
            op2=pop(); op1=pop();
            switch(token) {
                case plus: push(op1+op2); break;
                case minus: push(op1-op2); break;
                case times: push(op1*op2); break;
                case divide: push(op1/op2); break;
                case mod: push(op1%op2);
            } /* switch */
        } /* else */
        token = getToken(&symbol, &n);
    } /* while */
    return pop(); /* return result */
}
```
